

# ATLAS Group Meeting

Suchitoto Rose Tabares-Tarquinio

July 6 2021

# Introduction

## Topics Covered Today

- Control Region (CR) and Validation Region (VR) signal contamination study
  - Defining different cuts and regions to study
  - Calculating Data Yields and percentage of Signal Contamination of different cuts and regions
- Tight Photon ID Analysis
  - Look at distributions of photons that pass/fail the tight ID in our medium subsection.

# Regions and cuts

- Basic cuts
  - $(H_{\text{cand\_M}} > 60 \ \&\& \ H_{\text{cand\_M}} < 160) \ \&\& \ \text{abs}(d\text{Eta\_ph}) > 0.1$  ----> then decided to drop high  $H_{\text{cand\_M}}$  cut
- BDT cuts
  - $(\text{BDT\_score} > 0.0)$  vs  $(\text{BDT\_score} > 0.8)$
  - cut on the "bdtscore\_Hino\_Hyy" variable for signals with Hyy in the final state and "bdtscore\_Hino\_Zee" with Zee in the final state.
- CR (control region)
  - background-enriched region with negligible signal contamination
  - $\text{MET} < 20$
  - signal =  $\text{ph1\_t} > 0 \ \&\& \ \text{ph2\_t} > 0$  (PosPos)
  - dat (background) =  $\text{ph1\_t} > 0 \ \&\& \ \text{ph2\_t} > 0$  (PosPos)
- VR (validation region)
  - background and signal levels are predicted, but which are not used in the fit to constrain parameters
  - $(\text{MET} > 20 \ \&\& \ \text{MET} < 30)$  vs  $(\text{MET} > 20 \ \&\& \ \text{MET} < 35)$  -----> then decide to use 30 as MET cut
  - signal =  $\text{ph1\_t} > 0 \ \&\& \ \text{ph2\_t} > 0$  (PosPos)
  - dat (background) =  $\text{ph1\_t} < 0 \ \&\& \ \text{ph2\_t} < 0$  (NegNeg)
- SR (signal region)
  - signal-enriched region that drives the signal extraction but adds negligible constraints on the background parameters.
  - $(\text{MET} > 30)$  vs  $(\text{MET} > 35)$
  - signal =  $\text{ph1\_t} > 0 \ \&\& \ \text{ph2\_t} > 0$  (PosPos)
  - dat (background) =  $\text{ph1\_t} < 0 \ \&\& \ \text{ph2\_t} < 0$  (NegNeg)
- Using medium diphoton trigger. Each photon also passes the FCLoose isolation working point (WP) and has  $\text{maxEcell energy} > 10\text{GeV}$

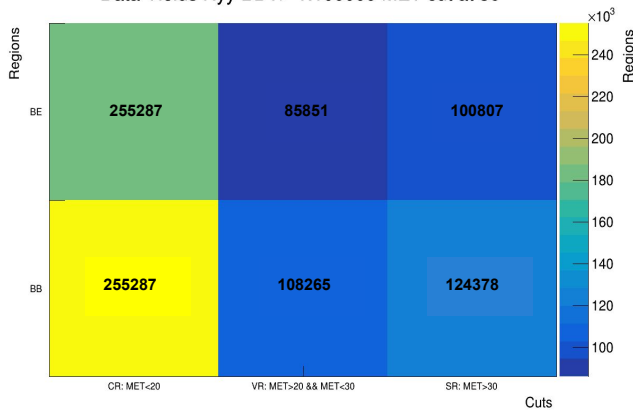

# Signal Contamination

Calculating percentage of Signal Contamination of different areas using MicroNTuples v6.0

- Data (background)
  - data\_97percent.root file.
- Signal
  - Hino files of final states HyyHSM and ZeeZSM with 2ns and 10ns lifetime and 100 GeV to 800 GeV mass.
- Signal Contamination percentage =  $100 \times \frac{SignalEvents}{DataEvents}$

# Data Yields with both Myy cuts (HCand\_M>60 && HCand\_M<160 GeV)

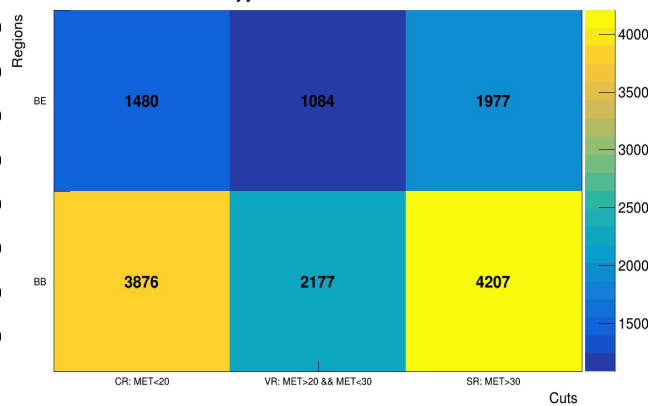

Data Yields Hyy BDT>-1.100000 MET cut at 30

Data Yields Hyy BDT>0.000000 MET cut at 30

Data Yields Hyy BDT>0.800000 MET cut at 30

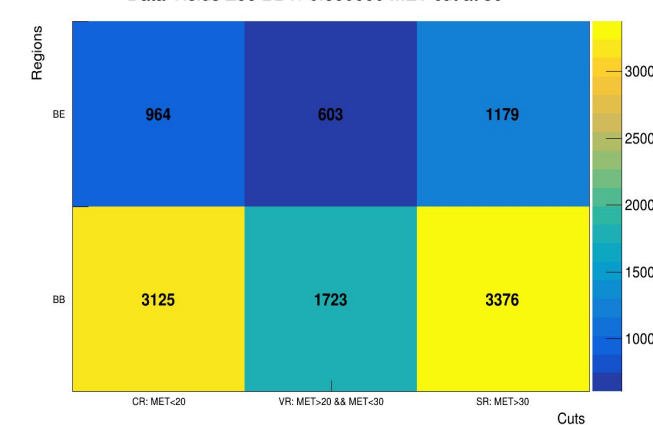

Data Yields Zee BDT>-1.100000 MET cut at 30

Data Yields Zee BDT>0.000000 MET cut at 30

Data Yields Zee BDT>0.800000 MET cut at 30

# Data Yields dropping upper Myy cut (only HCand\_M>60 GeV)

Data Yields Hyy BDT>-1.000000 MET cut at 30

Data Yields Hyy BDT>0.000000 MET cut at 30

Data Yields Hyy BDT>0.800000 MET cut at 30

Data Yields Zee BDT>-1.000000 MET cut at 30

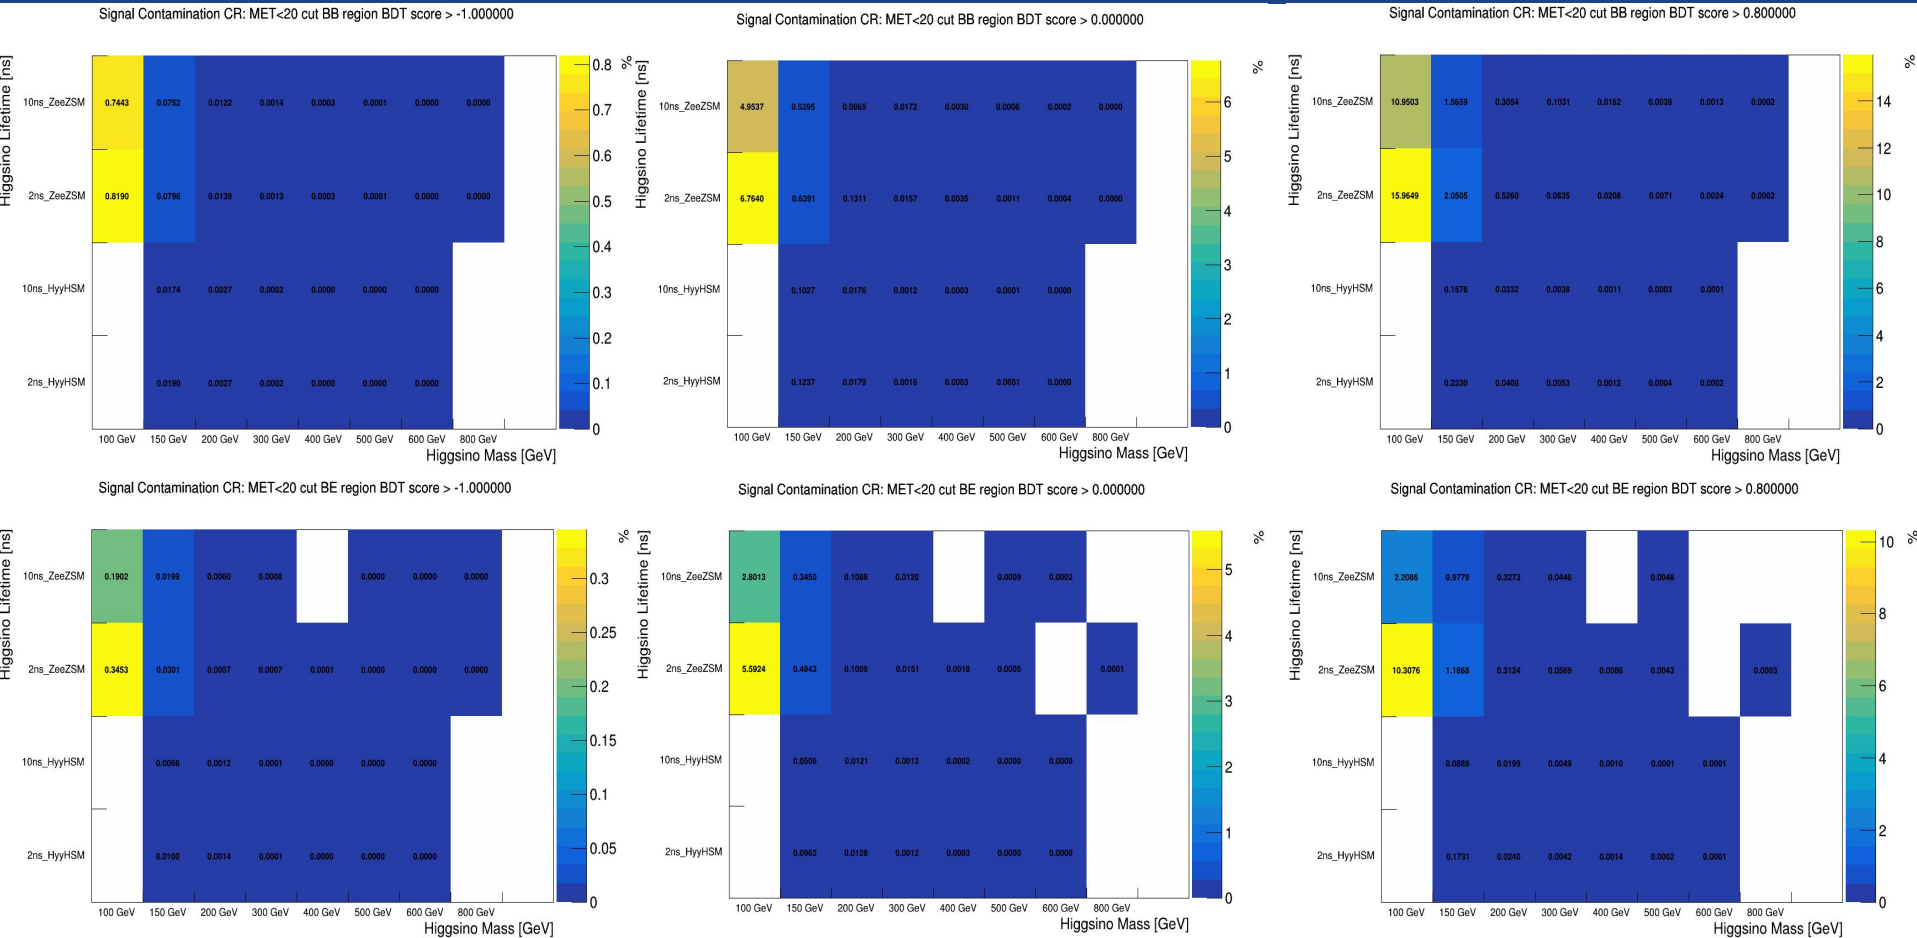

Data Yields Zee BDT>0.000000 MET cut at 30

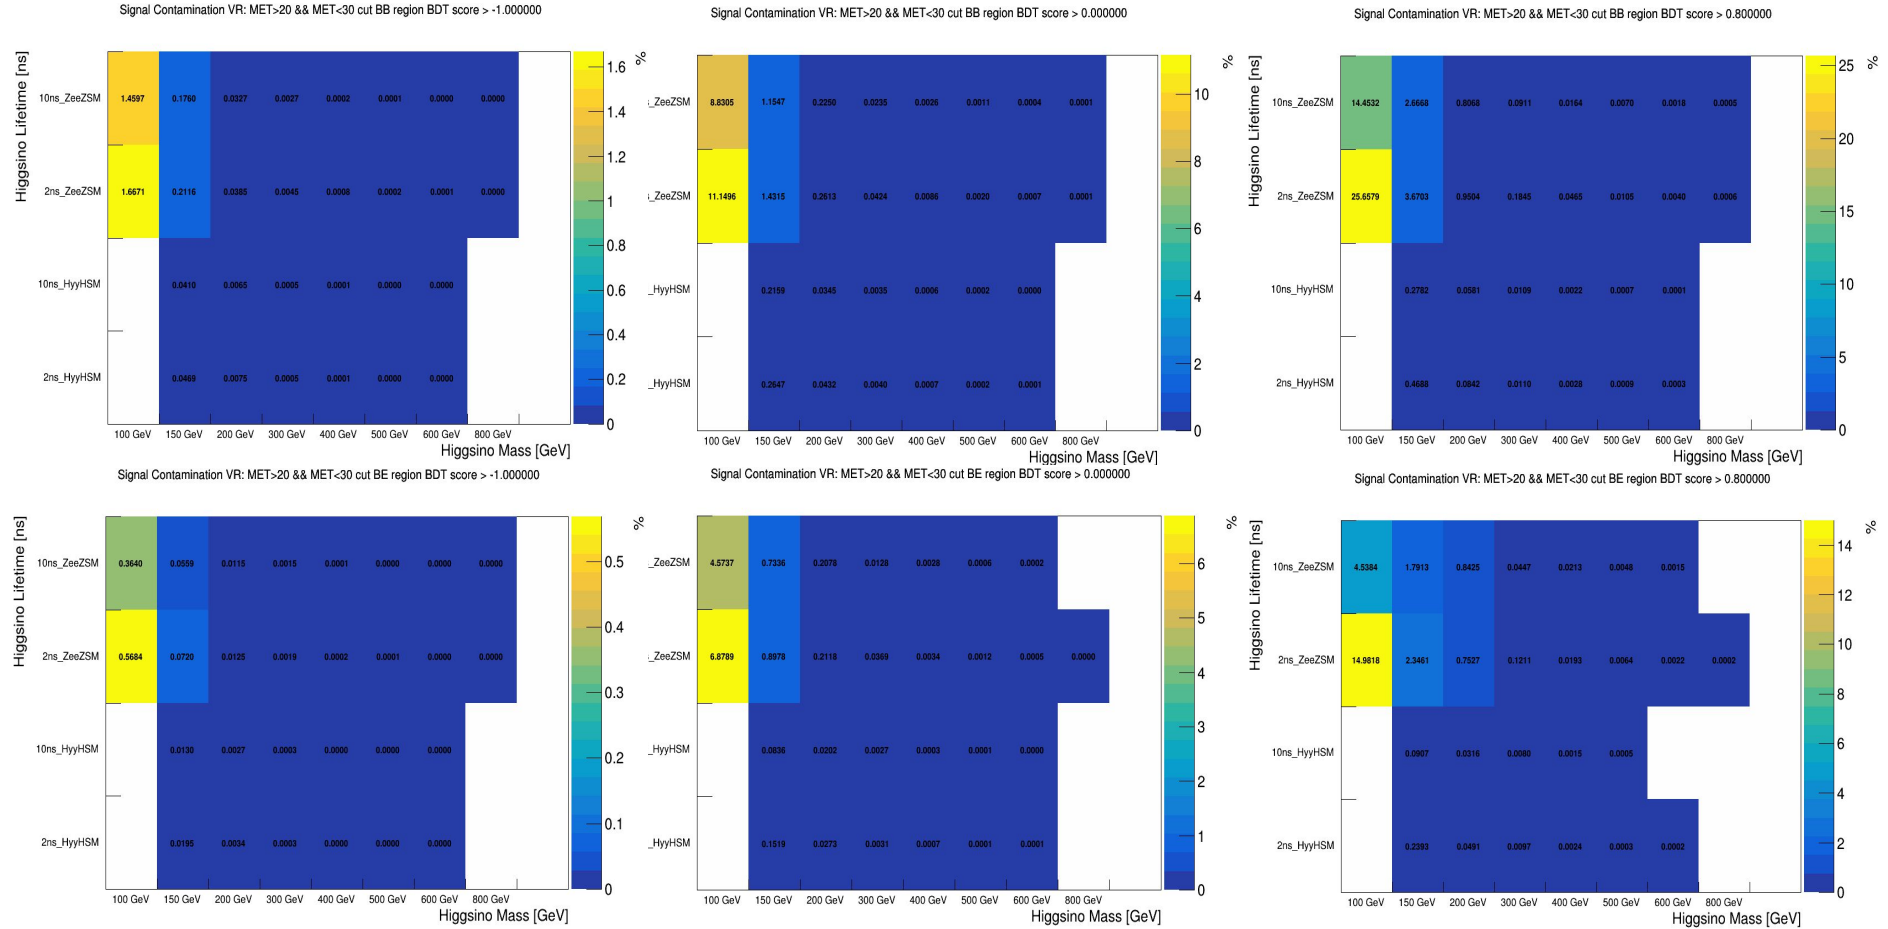

Data Yields Zee BDT>0.800000 MET cut at 30

# Signal Contamination for Control Region in Barrel-Barrel and Barrel-EndCap

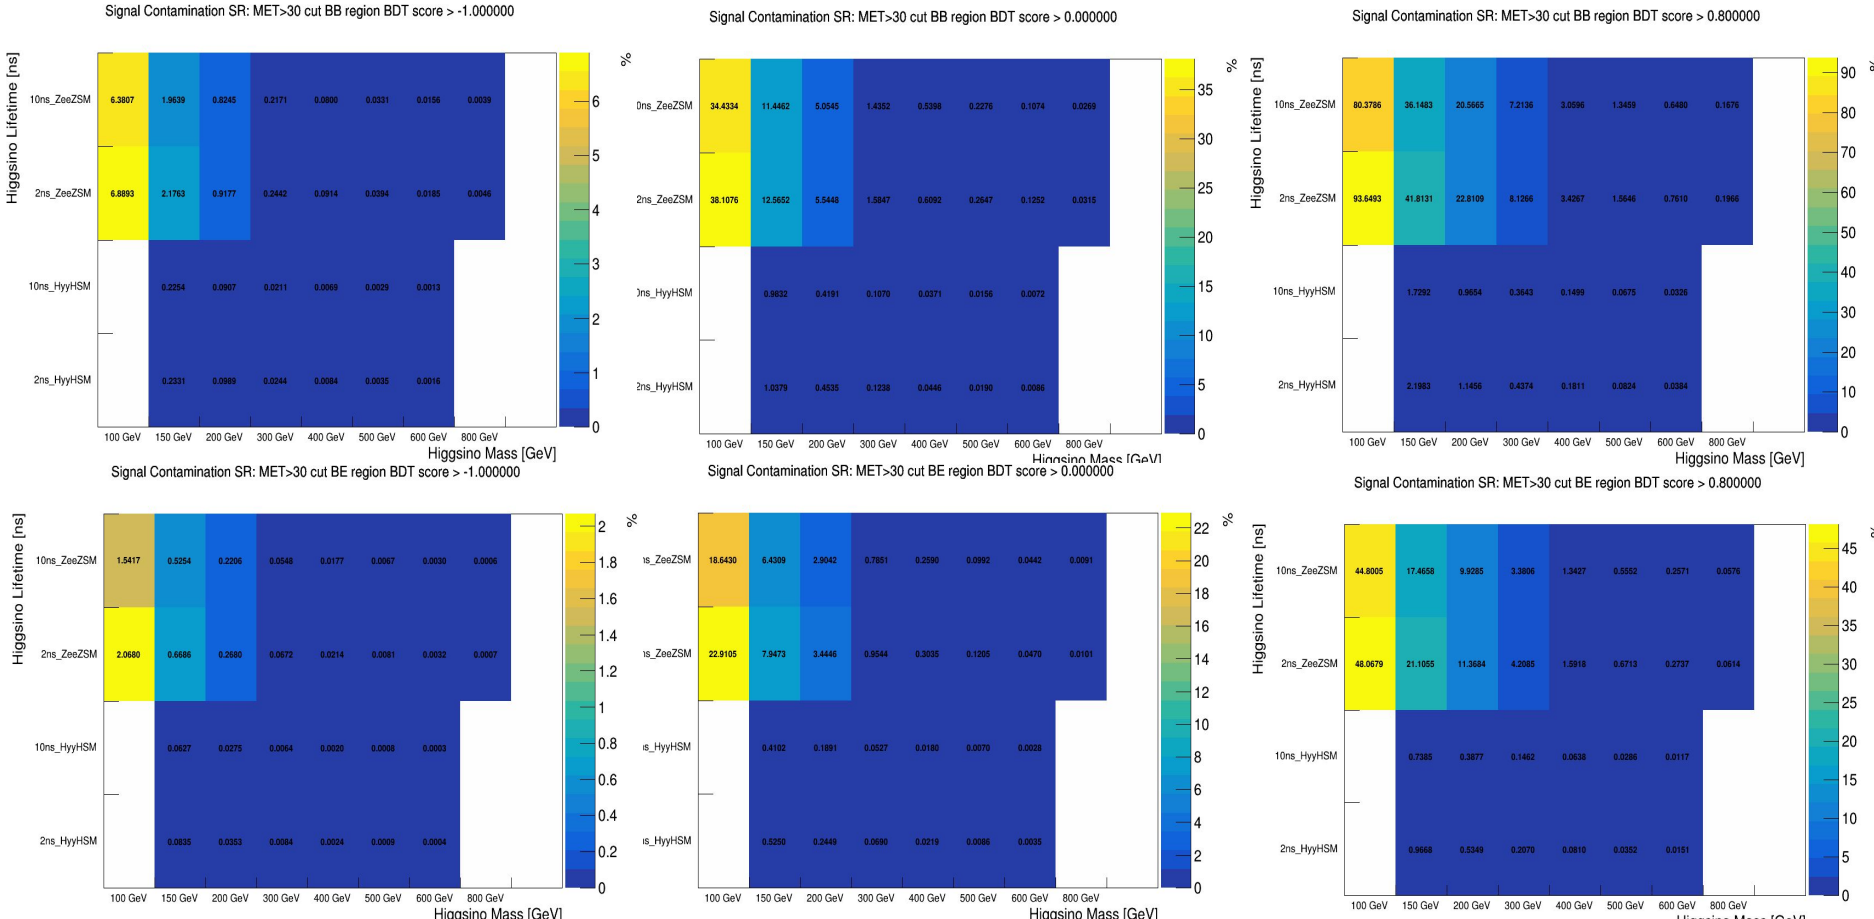

# Signal Contamination for Validation Region in Barrel-Barrel and Barrel-EndCap

# Signal Contamination for Signal Region in Barrel-Barrel and Barrel-EndCap

- Look at distributions of photons that pass/fail the tight ID in our medium subsection.
  - For each photon (isTight vs !isTight): leading/subleading pt, eta, E, maxEcell\_E, timing, pointing (ph1\_z)
  - For event-level variables ((ph1\_isTight && ph2\_isTight) vs (!ph1\_isTight || !ph2\_isTight)): vertexing, MET, Hcand\_pt, Hcand\_M, dEta\_ph, dPhi\_ph
  - all in Control Region: MET\_met < 20

# Conclusions & Next Steps

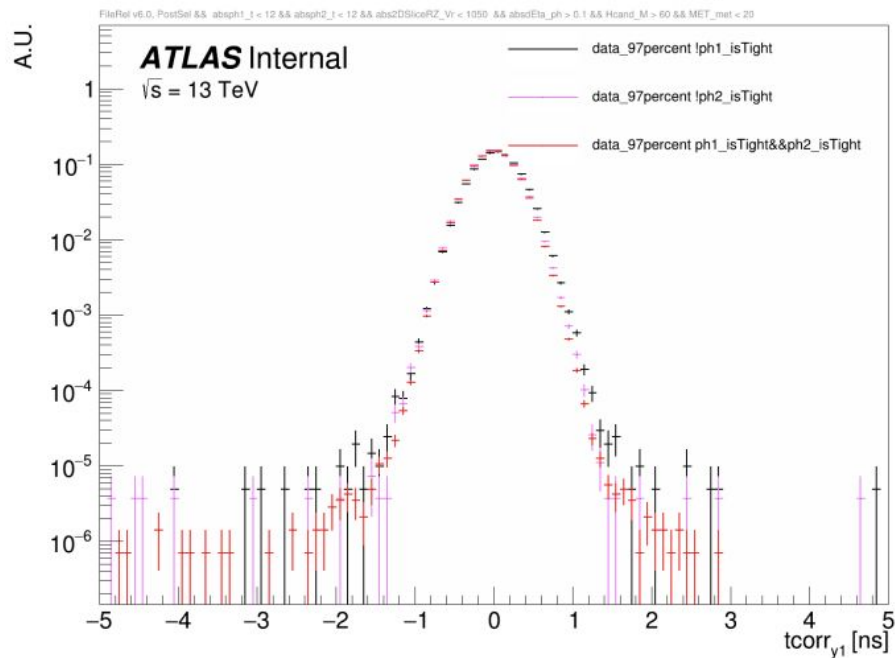

## Conclusions

- The precise value of BDT score cut has a significant impact on our signal contamination in both the CR and VR. The higher the BDT score cut, the higher the signal contamination.
- We must weight the pro's and con's concerning the MET cut dividing our VR and SR
  - A 30 GeV cut has higher signal contamination than a 35 GeV cut. A 35 GeV cut provides similar levels of background statistics between the VR and SR
  - So far decided to use 30 GeV and drop high  $M_{T\bar{T}}$  cut

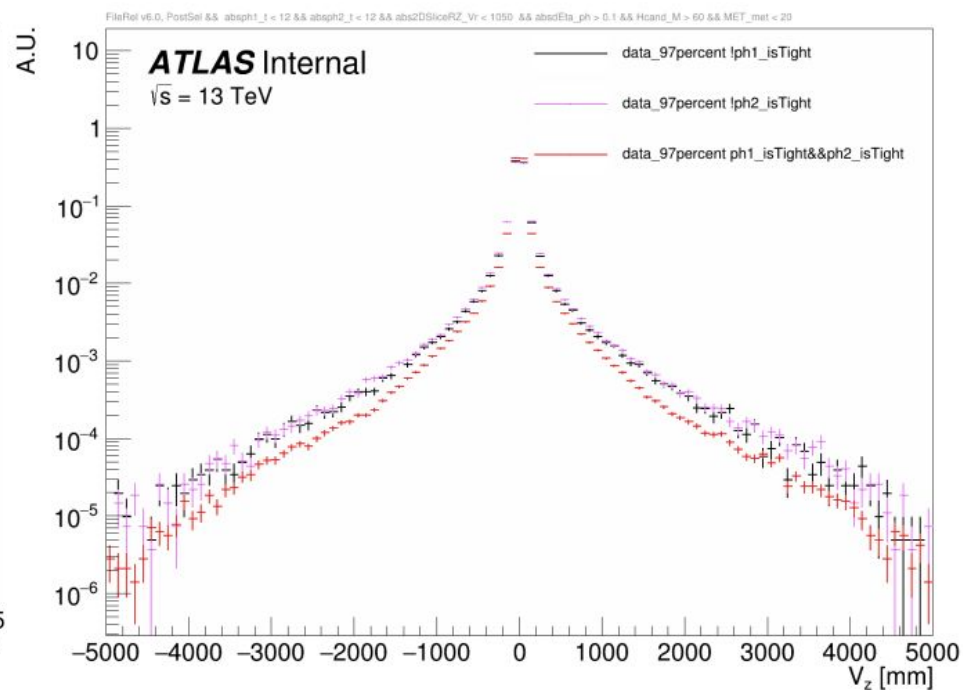

## Next Steps

- Start working on Tight Photon ID Analysis

## Lead Photon Corrected Timing

## Reco Vertex in Z

# Signal Contamination for Control Region

➤ CR in Barrel-Barrel  
above BDT\_score of 0.0 vs  
above BDT\_score of 0.8

➤ Control region  
stays at same  
cut (MET<20)

➤ CR in Barrel-Endcap  
above BDT\_score of 0.0 vs  
above BDT\_score of 0.8

Signal Contamination CR cut BB region BDT score > 0.0

Signal Contamination CR cut BB region BDT score > 0.8

Signal Contamination CR cut BE region BDT score > 0.0

Signal Contamination CR cut BE region BDT score > 0.8

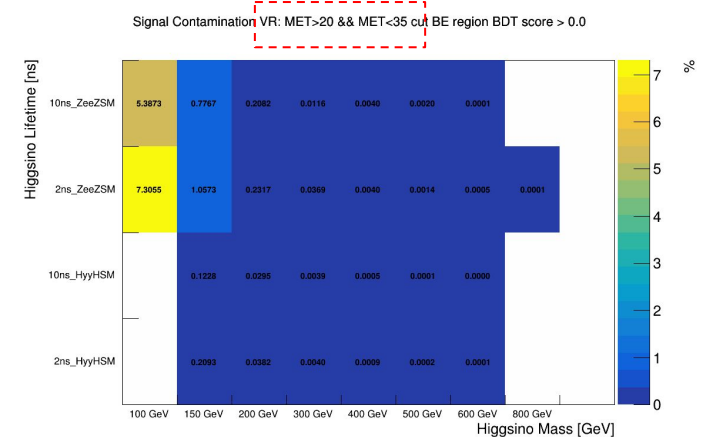

# Signal Contamination for Validation Region using BDT\_score >0.0

- Tight VR (MET 20-30) vs Loose (MET 20-35) in Barrel-Barrel above BDT\_score of 0.0

- Tight VR (MET 20-30) vs Loose (MET 20-35) in Barrel-Endcap above BDT\_score of 0.0

# Signal Contamination for Validation Region using BDT\_score >0.8

- Tight VR (MET 20-30) vs Loose (MET 20-35) in Barrel-Barrel above BDT\_score of 0.8

Signal Contamination VR cut BB region BDT score > 0.8

Signal Contamination VR: MET>20 && MET<35 cut BB region BDT score > 0.8

- Tight VR (MET 20-30) vs Loose (MET 20-35) in Barrel-Endcap above BDT\_score of 0.8

Signal Contamination VR cut BE region BDT score > 0.8

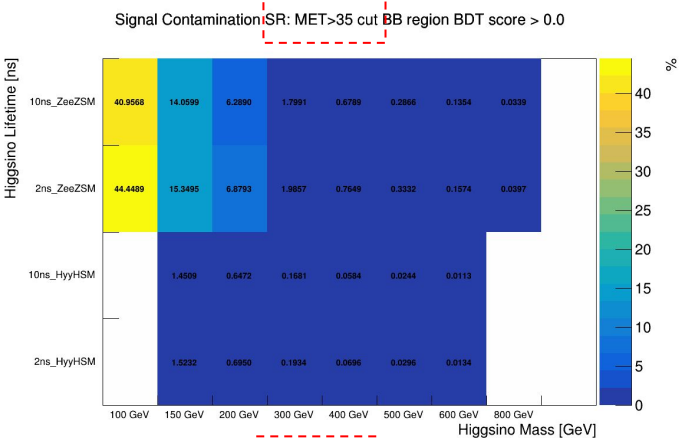

Signal Contamination VR: MET>20 && MET<35 cut BE region BDT score > 0.8

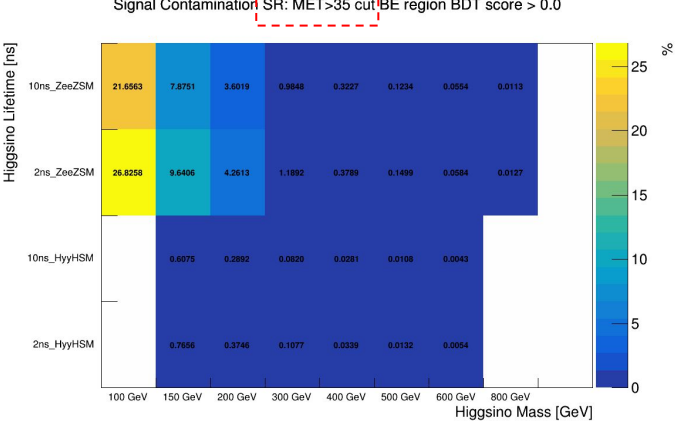

# Signal Contamination for Signal Region using BDT\_score >0.0

➤ SR as MET>30 vs  
SR as MET>35 in  
Barrel-Barrel above  
BDT\_score of 0.0

➤ SR as MET>30 vs  
SR as MET>35 in  
Barrel-Endcap above  
BDT\_score of 0.0

# Signal Contamination for Signal Region using BDT\_score >0.8

➤ SR as MET>30 vs  
SR as MET>35 in  
Barrel-Barrel above  
BDT\_score of 0.8

➤ SR as MET>30 vs  
SR as MET>35 in  
Barrel-Endcap above  
BDT\_score of 0.8
